

XRT Windowed Timing Mode – Trailing Charge

Andy Beardmore

University of Leicester

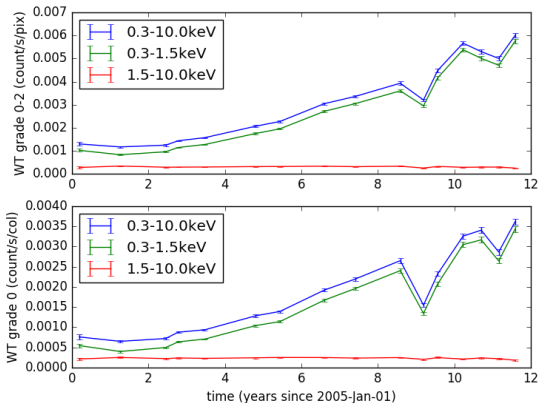

Lake Arrowhead, 2017-Mar-29

- CCD is clocked at a regular rate
- 10 rows are clocked into the serial register
- Central 200 columns are then read out of the serial register
 - readout time is 1.78 ms per output row
 - $10 \times 15\mu\text{s}$ (parallel) +
 - $205 \times 1.5\mu\text{s} + 200 \times 6.5\mu\text{s}$ (serial)
- Pseudo-frames (for telemetry) comprise 600 output rows
- WT mode selected automatically above ~ 5 c/s
- Piled-up above ~ 150 c/s (though depends on source spectrum)

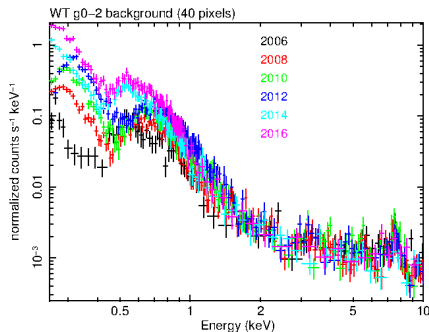

- WT background has been increasing with time – e.g. RXJ1856 :

- Background increases at low E (below ~ 1 keV)
- Low-E background $\sim 9\times$ higher in 2016 c.f. 2006

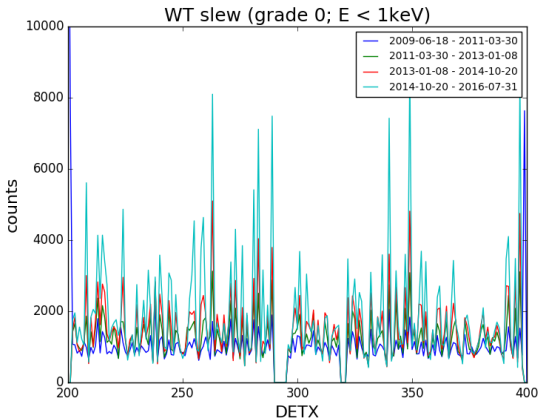

- RXJ1856 WT background spectra
 - Observed 1 or 2 times per year since launch
 - 20 ks per observation — i.e. up to 40 ks per year

- Onboard event Threshold changed 80 \rightarrow 60DN on 2013-Dec-11
 - Slight reduction in grade 0 low energy rise after change

- WT slew data – count level evolution :

- WT trap depths in 2016 (from Beatriz) :

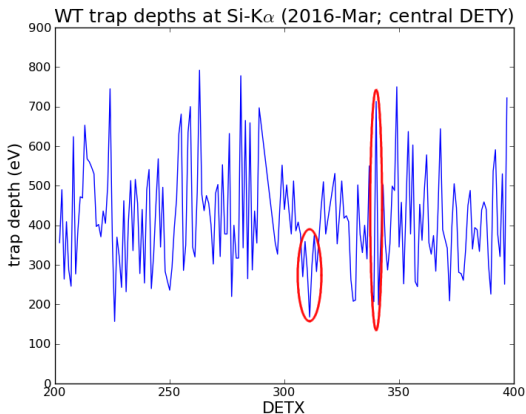

- WT trap depths in 2016 (from Beatriz) :

- → background count rate increase associated with columns containing deep traps.

- WT trap depths in 2016 (from Beatriz) :

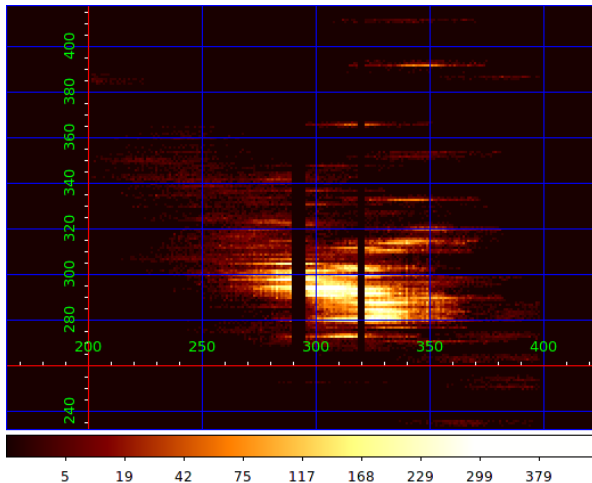

- Highlighted columns show DETX=311 (shallow trap) and 340 (deep trap)

- Merged E0102 2013–2016 data

- Merged E0102 2013–2016 data

- Compare spectra from columns with different trap depths.

- Merged E0102 2013–2016 data
- DETX : 309 (blue: medium trap), 311 (green: shallow trap) in PHA
- DETX : 309 (blue: medium trap), 311 (green: shallow trap) in PI

- Merged E0102 2013–2016 data
- DETX : 339 (blue: shallow trap), 340 (green: deep trap) in PHA
- DETX : 339 (blue: shallow trap), 340 (green: deep trap) in PI

- Merged E0102 2013–2016 data
- DETX : 339 (blue: shallow trap), 340 (green: deep trap) in PHA
- DETX : 339 (blue: shallow trap), 340 (green: deep trap) in PI

- Columns with deep traps show a significant low energy excess

- Gas A 2015 data (central DETY)

- DETX : 339 (green: deep), 340 (blue: shallow) in PHA

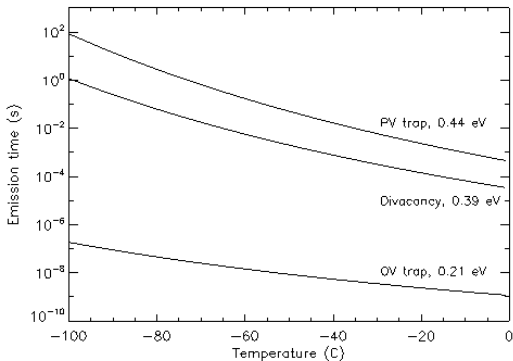

- DETX : 339 (green: deep), 340 (blue: shallow) in PI

- Columns with deep traps show a significant low energy excess

- Origin of the low energy excess is thought to be deferred charge released from charge traps \rightarrow causing trailing charge
- Trap emission time scale :

- Claudio found trap energy level ~ 0.35 eV and emission times $\sim 10\times$ parallel transfer time – i.e. of order the WT readout timescale (1.78ms)

- Expect charge traps to release a fraction of the trapped charge into rows following the one the X-ray interaction occurs in.
- In WT mode, 10 parallel rows are clocked into the serial register before the latter is read out.
 - assigned a RAWY coordinate (range 0–599) in each WT pseudo-frame
- Wrote C++ code to test if an event occurs in the same column as, but immediately following, an event in the previous row (based on RAWY) → flag as a TRAILING event, if so. Two methods :
 - (i) : Only flag if PHA is less than PHA in previous row
 - (ii) : Flag is PHA is less than a threshold PHA
- Flagged events can then be removed from the event list

- E0102 2016 data

- DETX : 339 (shallow trap)

- DETX : 340 (deep trap)

NB : blue peaks at 125 counts !

- E0102 2016 data

- DETX : 339 (shallow trap)

- DETX : 340 (deep trap)

NB : blue peaks at 125 counts !

- Low E excess considerably reduced

- Cas A (2015)

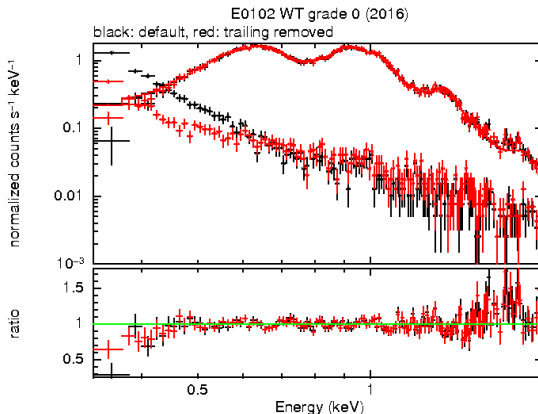

- PHA

- PI

- E0102 – grade 0

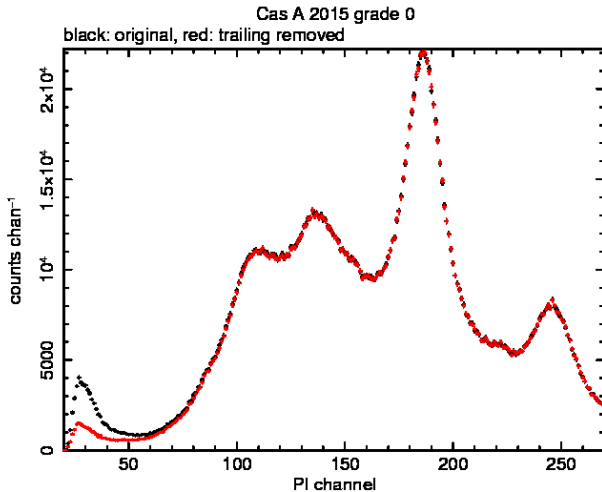

apb27-Mar-2017 16:01

- Data with trailing charge removed (red) has better low energy background subtraction

- Cas A – grade 0

- Previously noted that the WT background is increasing – e.g. RXJ1856 :

- Removing trailing charge reduces background by 40 per cent (below ~ 1 keV)
- Equivalent to level of 6 years ago

- WT background has increased slowly with time
- Identified with trailing charge released from the deepest charge traps → forms low energy events in following rows
- Wrote code which attempts to isolate the trailing charge
 - Preprocess unfiltered event files to tag the trailing events then remove them
 - Can identify/remove ~ 60 per cent of low E events in trapped columns
- Can algorithm be improved ?
 - Could, in principle, recombine trailing charge with its parent event.
