

N132D observations with eROSITA

Spectra of **N132D** obtained in the **first 3 eRosita All-Sky Surveys** (‘eRASS1, eRASS2, eRASS3’) were analysed to check the current energy calibration ($\approx 1.8\text{-}2.0$ ks per TM and eRASS)

This was done individually for each survey, for each TM, for singles and for all valid patterns, using the IACHEC¹ and an empirical² model of N132D.

¹v2.14, ²based on the fit of the RGS data by Suzuki et al. (2020) for the low-energy part and a VNEI component for the high-energy part fitted by A. Foster to EPIC-pn and MOS data

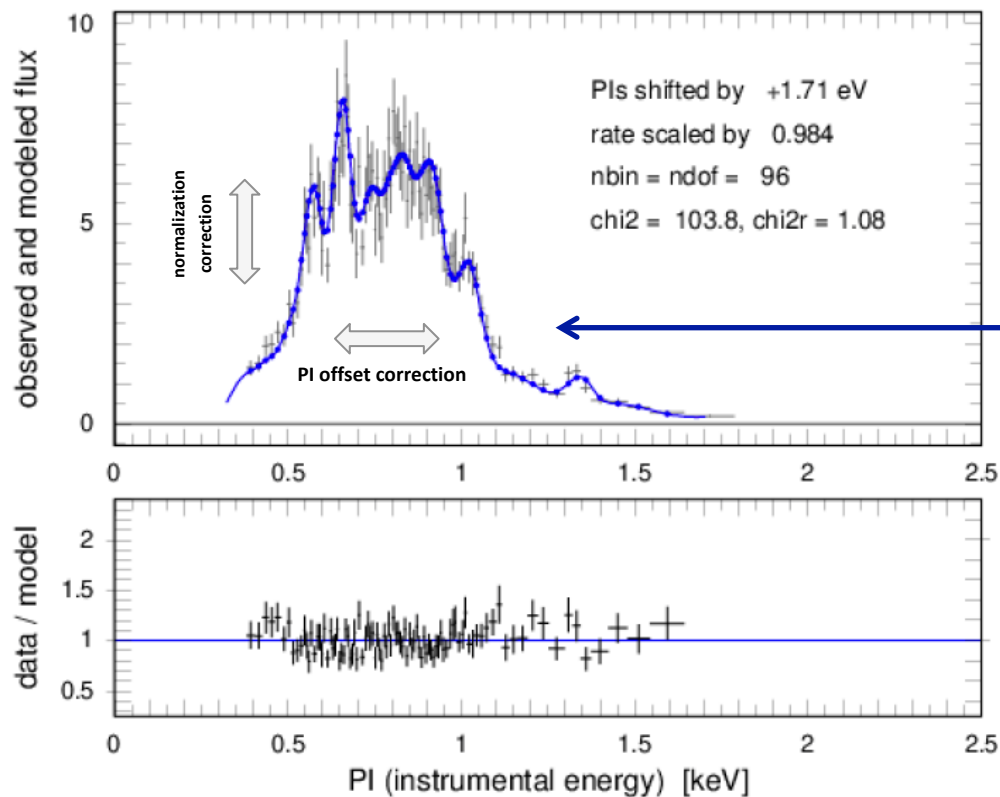

→ 3 surveys, 7 TMs, 2 pattern selections, 2 spectral models → $3 \times 7 \times 2 \times 2 = 84$ spectra

Main goal: check for internal consistency of two major calibration quantities:
energy scale and **flux normalization**

Method:

1. use the spectral model **without any modification**, multiply it with the ARF and fold it through the RMF (only this step makes use of XSPEC)
2. interpolate the folded spectrum, so that it can be evaluated at any PI value
3. compose a χ^2 **map** for a grid of **[energy offset, normalization correction]** by shifting the measured PI values and scaling the counts, and computing the χ^2 for each grid point

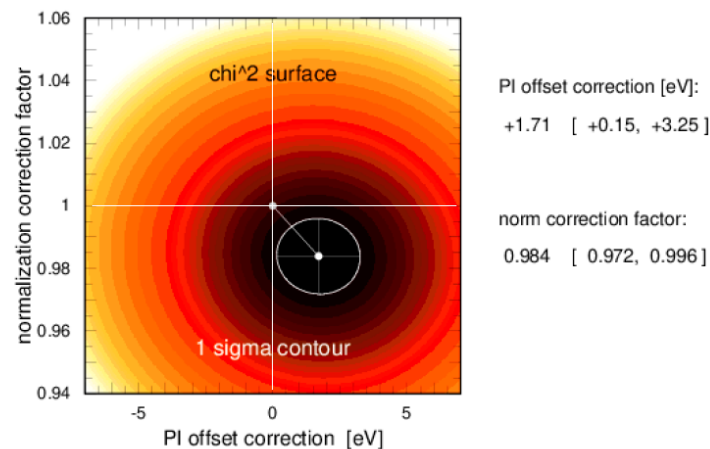

Example: TM4 in eRASS2, using just singles, with IACHEC model spectrum of N132D

unmodified „fixed“ IACHEC spectrum, just multiplied with ARF and folded through RMF, and spline-interpolated

the **observed** spectrum is allowed to be shifted horizontally and scaled vertically

resulting χ^2 surface:

s_n132d_em01_120_emp.qdp

example:

TM1
eRASS1
singles only

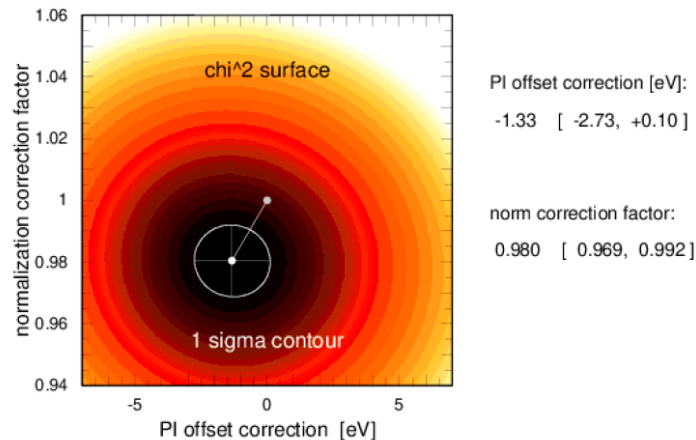

IACHEC model

physical model

s_n132d_em01_120_phy.qdp

n132d_em01_120_emp.qdp

example:

TM1
eRASS1
all valid patterns

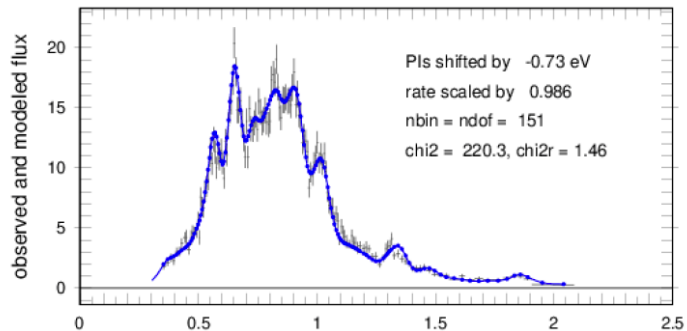

IACHEC model

physical model

n132d_em01_120_phy.qdp

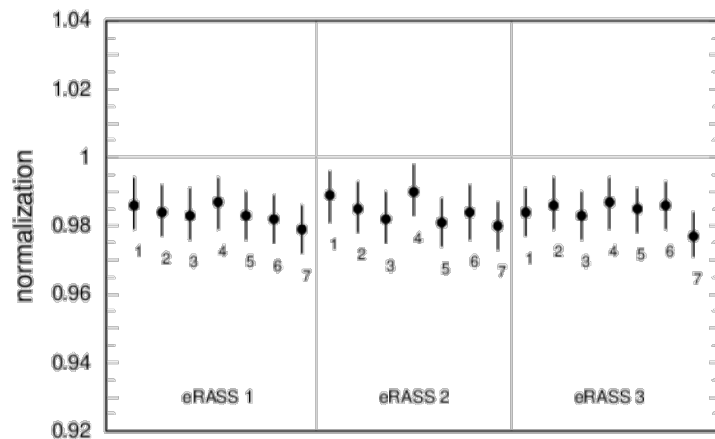

N132D, eSASS 947 processing, singles only

IACHEC model

N132D, eSASS 947 processing, all patterns

IACHEC model

1 σ error bars

N132D, eSASS 947 processing, singles only

physical model

N132D, eSASS 947 processing, all patterns

physical model

1σ error bars

N132D observations with eROSITA

Summary:

1. normalization: consistently too low by $\approx 2\%$
 2. energy scale:
 - accurate to $\approx \pm 1$ eV for IACHEC model
 - larger deviations for physical model
- no systematic temporal trend over 1½ years
no obvious differences between TMs

Thanks to the IACHEC work on the N132D model spectrum it is possible to determine the absolute energy scale of each eROSITA TM in the energy range 0.5 – 1.1 keV for an exposure time of ≈ 2 ks to an accuracy of ± 1 eV.
